

Executive Summary

- VITL is a MetaDyn medical simulation experience where a learner communicates with the mother of an infant patient in a guided simulation.
- The product is moving beyond a simple AI conversation into a structured simulation with activity progression, communication scoring, and assessment.

Why It Matters

- VITL demonstrates a higher-value MetaDyn product direction: scenario-driven immersive training that combines AI interaction with structured simulation.
- This creates a path toward more credible teaching, review, and assessment workflows over time.

Current Milestone

- The current milestone is to validate a working learner loop from greeting and rapport into structured patient-history intake.
- The first milestone is intentionally bounded to prove the experience flow before expanding into heavier assessment or reporting.

System Components

- Voice/controller layer for text, voice, transcription, model responses, and speech output.
- Simulation manager for activity flow, state, scoring hooks, escalation, and hidden scenario context.
- Communication scoring service for rubric-based learner scoring.
- Planned patient-intake layer for structured documentation of learner-collected history.

Bottom Line

- The near-term value is a coherent simulation loop where communication quality affects progression and structured history capture.
