

Project Summary

- VITL is evolving from a simple conversational prototype into a structured simulation product with scenario logic, learner assessment, and reporting.
- The active case is a pediatric infant UTI encounter focused on communication with the infant's mother.

What Matters Right Now

- Simulation-aware routing between MetaDynVoiceController and VITLSimulationManager is a central part of the current design.
- Model-backed communication scoring through OpenRouter is the intended primary scoring path, with fallback scoring preserved.
- Activity 2 should capture learner-entered patient history as structured runtime data rather than inferred LLM extraction.

Milestone 1 Scope

- Greeting / rapport flow.
- Threshold-based activity progression.
- Simulation-aware mother response after scoring.
- Structured history intake as a distinct Activity 2 flow.
- Analytics-safe milestone events where useful.

Out of Scope

- Full automated clinical grading.
- Automatic extraction of structured history from mother dialogue.
- Complete reporting/export stack.
- Large-scale rewrite of string-based event surfaces.

Operational Read

- The strongest architectural line in the current VITL material is separation of concerns: conversation history, learner scoring, simulation logic, and reporting.
- That separation should stay intact as implementation moves forward.
